# Note about sequences of extremal ( $A, 2 B$ )-edge coloured trees 

#### Abstract

In this paper we determine successive extremal trees with respect to the number of all $(A, 2 B)$-edge colourings.

1. Introduction. For concepts not defined here see [4]. Let $G$ be an undirected, connected and simple graph with the vertex set $V(G)$ and the edge set $E(G)$. Then the order (number of vertices) and the size (number of edges) of $G$ is denoted by $n$ and $m$, respectively. Let $G(m)$ be a graph of size $m$. Then $P(m), C(m), T(m)$ and $S(m)$ denote a path, a cycle, a tree and a star of size $m$, respectively.

Let $P\left(m_{1}, m-m_{1}-1\right)$ be a 2 -palm of size $m, m \geq 5$ and the diameter 3 with two support vertices $x, y \in V\left(P\left(m_{1}, m-m_{1}-1\right)\right)$. Suppose that the support vertex $x$ is adjacent to $m_{1}$ leaves, then the vertex $y$ is adjacent to $m-m_{1}-1$ leaves.

In a tree, a vertex of degree at least 3 is a branch vertex, a vertex of degree 1 is a leaf. If a tree has exactly three leaves, then it is named a tripod. In other words, every tripod has the unique branch vertex and consequently this branch vertex is the initial vertex of three elementary paths. Let $m \geq 3$, $p \geq 1, t \geq 1$ be integers. Then $T(m, p, t)$ denotes a tripod of size $m$ and three paths of length $p, t$ and $m-p-t$ with the branch vertex as the initial vertex of these paths. For convenience a path of length $i, i \geq 1$ we denote shortly by $i$-path.

[^0]Let $b_{m}$ be the number of all nonisomorphic tripods of size $m$. Then it is given by the following recurrence relation $b_{m}=1+b_{m-2}+b_{m-3}-b_{m-5}$, for $m \geq 5$ with initial conditions $b_{0}=b_{1}=b_{2}=0, b_{3}=b_{4}=1$, see [9], [10].

The $n$th Fibonacci number $F_{n}$ is defined recursively as follows: $F_{n}=$ $F_{n-1}+F_{n-2}, n \geq 2$ with $F_{0}=F_{1}=1$.

The telephone numbers $t(n)$ are defined by the recurrence relation $t(n)=$ $t(n-1)+(n-1) t(n-2)$, for $n \geq 2$ with $t(0)=t(1)=1$.

Fibonacci and telephone numbers have many interesting applications and interpretations also in graphs. Fibonacci numbers have a graph interpretation known as the Merrifield-Simmons index (i.e. the number of all independent sets) of the $n$-vertex path $P_{n}$, see [5], [6], [7, p. 85-86].

Telephone numbers have also a graph interpretation known as the Hosoya index (i.e. the number of all matchings) of the $n$-vertex complete graph $K_{n}$. For details see [8].

In [1] and [2] there was introduced the graph interpretation of Fibonacci numbers and telephone numbers with respect to the special edge colourings of a graph. We recall this definition.

Let $\mathcal{C}=\{A, B\}$ be the set of two colours. A graph $G$ is $(A, 2 B)$-edge coloured if for every maximal $B$-monochromatic subgraph $H$ of $G$ there is a partition of $H$ into edge disjoint paths of length 2. Clearly $(A, 2 B)$-edge colouring always exists, since we have no restriction on the colour $A$.

Let $\mathcal{L}$ be a family of all distinct $(A, 2 B)$-edge coloured graphs obtained by $(A, 2 B)$-colouring of a graph $G$. Then $\mathcal{L}=\left\{G^{(1)}, G^{(2)}, \ldots, G^{(r)}\right\}, r \geq 1$, where $G^{(p)}, 1 \leq p \leq r$ denotes a graph obtained by $(A, 2 B)$-edge colouring of a graph $G$. For $(A, 2 B)$-edge coloured graph $G^{(p)}, 1 \leq p \leq r$ by $\theta\left(G^{(p)}\right)$ we denote the number of all partitions of $B$-monochromatic subgraphs of $G^{(p)}$ into edge disjoint paths of length 2. For the explanation, if $G^{(p)}$ is $A$ monochromatic, then we put $\theta\left(G^{(p)}\right)=1$. The number of all $(A, 2 B)$-edge colourings we define as the graph parameter

$$
\sigma_{(A, 2 B)}(G)=\sum_{p=1}^{r} \theta\left(G^{(p)}\right) .
$$

The parameter $\sigma_{(A, 2 B)}(G)$ was determined for paths, cycles and bounded for trees, for details see [1], [2], [3]. In this paper we give sequences of $(A, 2 B)$ extremal trees, i.e. consecutive trees with extremal values of the parameter $\sigma_{(A, 2 B)}(T(m))$.
2. Main results. In [2], the lower bound and the upper bound of the parameter $\sigma_{(A, 2 B)}(T(m)), m \geq 1$ were given. Moreover, in [1] it was proved that the upper bound is realized by telephone numbers. This result is presented in the following theorem.

Theorem 1 ([1], [2]). Let $T(m)$ be a tree of size $m, m \geq 1$. Then

$$
F_{m} \leq \sigma_{(A, 2 B)}(T(m)) \leq t(m)
$$

Moreover, $\sigma_{(A, 2 B)}(T(m))=F_{m}$ for $T(m) \cong P(m)$ and $\sigma_{(A, 2 B)}(T(m))=$ $t(m)$ for $T(m) \cong S(m)$.

Next in [1] the following estimations for the parameter $\sigma_{(A, 2 B)}(T(m, p, t))$ in the class of tripods were proved:
Theorem 2 ([1]). Let $m \geq 3$ be an integer. If $T(m) \nsubseteq P(m)$ and $T(m) \nsubseteq$ $T(m, p, t)$ for all $p \geq 1, t \geq 1$, then

$$
\sigma_{(A, 2 B)}(P(m)) \leq \sigma_{(A, 2 B)}(T(m, p, t)) \leq \sigma_{(A, 2 B)}(T(m))
$$

From the above theorems it is clear that a path $P(m)$ is the extremal tree achieving the minimum value of $\sigma_{(A, 2 B)}(T(m))$. Moreover, if we want to find the next successive smallest trees with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$ we have to study the whole class of tripods. The maximum and minimum value of $\sigma_{(A, 2 B)}(T(m, p, t))$ were established in [3].
Theorem 3 ([3]). Let $m \geq 4, p \geq 1, t \geq 1$ be integers. Then

$$
F_{m-1}+2 F_{m-3} \leq \sigma_{(A, 2 B)}(T(m, p, t)) \leq 2 F_{m-1}
$$

Moreover, $\sigma_{(A, 2 B)}(T(m, p, t))=2 F_{m-1}$ if $T(m, p, t) \cong T(m, 1,1)$ and $\sigma_{(A, 2 B)}(T(m, p, t))=F_{m-1}+2 F_{m-3}$ if $T(m, p, t) \cong T(m, 2,2)$.

From Theorem 2 and Theorem 3 we can deduce that the tripod $T(m, 2,2)$ is the second smallest tree with respect to the $\sigma_{(A, 2 B)}(T(m))$. In [1] there was found the second minimal tripod $T(m, 4,2)$ with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$ which is also, by Theorem 2, the third smallest in the class of trees. From Theorem 3 it is obvious that the $\operatorname{tripod} T(m, 1,1)$ is the largest in the class of tripods with respect to $\sigma_{(A, 2 B)}(T(m, p, t))$. If we investigate the whole class of tripods, we obtain the sequence of successive extremal tripods from the minimal $T(m, 2,2)$ to the maximal $T(m, 1,1)$.

Let $T(m, p, t)$ be an arbitrary tripod, where $m \geq 4, p \geq 1, t \geq 1$. For $t=$ $2,4, \ldots,\left\lfloor\frac{m}{3}\right\rfloor, \ldots, 3,1$ we obtain the successive smallest tripods with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$. The integer $t$ assumes the consecutive even numbers from 2 to $\left\lfloor\frac{m}{3}\right\rfloor$, if $\left\lfloor\frac{m}{3}\right\rfloor$ is even or to $\left\lfloor\frac{m}{3}\right\rfloor-1$, if $\left\lfloor\frac{m}{3}\right\rfloor$ is odd. Then $t$ assumes the consecutive odd numbers from $\left\lfloor\frac{m}{3}\right\rfloor$ or $\left\lfloor\frac{m}{3}\right\rfloor-1$ to 1 . In other words, the tripod $T(m, p, 2)$ always achieves the smallest value of $\sigma_{(A, 2 B)}(T(m, p, t))$ and the tripod $T(m, p, 1)$ always achieves the largest value of this parameter.

Moreover, for each value of $t$ we can construct a sequence of extremal tripods with respect to the integer $p$.

If $t=1$, then the successive smallest tripods are given respectively for $p=2,4, \ldots,\left\lfloor\frac{m-1}{2}\right\rfloor, \ldots, 3,1$.

If $t=2$, then $p=2,4, \ldots,\left\lfloor\frac{m-2}{2}\right\rfloor, \ldots, 5,3$.

If $t=3$, then $p=4,6, \ldots,\left\lfloor\frac{m-3}{2}\right\rfloor, \ldots, 5,3$.
If $t=4$, then $p=4,6, \ldots,\left\lfloor\frac{m-4}{2}\right\rfloor, \ldots, 7,5$.
$\vdots$
If $t=\left\lfloor\frac{m}{3}\right\rfloor$ and $\left\lfloor\frac{m}{3}\right\rfloor$ is even, then $p=\left\lfloor\frac{m}{3}\right\rfloor, \ldots,\left\lfloor\frac{m-\left\lfloor\frac{m}{3}\right\rfloor}{2}\right\rfloor, \ldots,\left\lfloor\frac{m}{3}\right\rfloor+1$, and if $\left\lfloor\frac{m}{3}\right\rfloor$ is odd, then $p=\left\lfloor\frac{m}{3}\right\rfloor+1, \ldots,\left\lfloor\frac{m-\left\lfloor\frac{m}{3}\right\rfloor}{2}\right\rfloor, \ldots,\left\lfloor\frac{m}{3}\right\rfloor$.

For example if we consider the tripods $T(12, p, t)$ for all possible $p, t$, then the sequence of successive smallest tripods with respect to the increasing parameter $\sigma_{(A, 2 B)}(T(m, p, t))$ is as follows

$$
\begin{aligned}
& T(12,2,2), T(12,4,2), T(12,5,2), T(12,3,2), T(12,4,4), T(12,4,3), \\
& T(12,3,3), T(12,2,1), T(12,4,1), T(12,5,1), T(12,3,1), T(12,1,1) .
\end{aligned}
$$

The above considerations give an answer to the question given in [1].
Let $t_{i}(m), i=1, \ldots, b_{m+1}$ be the $i$ th minimum tree of size $m$ with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$. Then

$$
\begin{aligned}
& t_{1}(m) \cong P(m), t_{2}(m) \cong T(m, 2,2), t_{3}(m) \cong T(m, 4,2), \\
& t_{4}(m) \cong T(m, 6,2), \ldots, t_{m-1}(m) \cong T(m, 5,1), \\
& t_{m}(m) \cong T(m, 3,1), t_{m+1}(m) \cong T(m, 1,1) .
\end{aligned}
$$

Now we determine the successive trees with respect to the decreasing parameter $\sigma_{(A, 2 B)}(T(m))$. To do this we use among others the following lemma.
Lemma 1 ([2]). Let $G=H \cup T(l) \cup\{e\}$ be a connected graph, where $H$ is a connected graph, $T(l)$ is a tree of size $l, l \geq 1$ and $H$ and $T(l)$ are vertex disjoint. Assume that $e=u v$, where $u \in V(H)$ and $v \in V(T(l))$. Then

$$
\begin{equation*}
\sigma_{(A, 2 B)}(H \cup P(l) \cup\{e\}) \leq \sigma_{(A, 2 B)}(G) \leq \sigma_{(A, 2 B)}(H \cup S(l) \cup\{e\}), \tag{1}
\end{equation*}
$$

where the vertex $v$ is identified with the center of the star $S(l)$. Moreover, the equality holds if $T(l) \cong P(l)$ or $T(l) \cong S(l)$.
Theorem 4. Let $m \geq 5, m_{1} \geq 2$ be integers. Then

$$
\sigma_{(A, 2 B)}(T(m)) \leq \sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-1\right)\right) \leq \sigma_{(A, 2 B)}(S(m))
$$

Proof. The inequality $\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-1\right)\right) \leq \sigma_{(A, 2 B)}(S(m))$ follows immediately from Theorem 1. Let $T(m) \not \equiv S(m)$ and $T(m) \not \equiv P\left(m_{1}, m-\right.$ $\left.m_{1}-1\right)$. Then $\operatorname{diam} T(m) \geq 4$. Let $\bar{P}=x-y$ be the path which realizes the diameter $\operatorname{diam} T(m)$. Then $x, y \in V(T(m))$ are leaves. Let $u \in V(T(m))$ be adjacent to the vertex $x$ and the edge $e \in \bar{P}$ be incident with $u$ and $e$ is not incident with a leaf. Then $T(m)=T\left(m_{1}\right) \cup T\left(m_{2}\right) \cup\{e\}$, where $m_{1}+m_{2}+1=m$. Applying Lemma 1, we have $\sigma_{(A, 2 B)}(T(m)) \leq \sigma_{(A, 2 B)}\left(S\left(m_{1}\right) \cup S\left(m_{2}\right) \cup\{e\}\right)=\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-1\right)\right)$, which ends the proof.

Let $T_{i}(m)$ be the $i$ th maximum tree of size $m$ with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$.

Theorem 5. Let $m \geq 5$ be an integer. Then $T_{1}(m)=S(m), \sigma_{(A, 2 B)}(S(m))$ $=t(m)$ and $T_{i}(m)=P(m-i, i-1)$ for $2 \leq i \leq m-\left\lceil\frac{m-1}{2}\right\rceil$.
Theorem 6. Let $m \geq 5, m_{1} \geq 2$ be integers. If $T(m) \nsupseteq S(m)$ and $T(m) \nexists$ $P\left(m_{1}, m-m_{1}-1\right)$, then $\sigma_{(A, 2 B)}(T(m)) \leq \sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)$.
Proof. Since $T(m) \nsubseteq S(m)$ and $T(m) \nsubseteq P\left(m_{1}, m-m_{1}-1\right)$ then diam $T(m)$ $\geq 4$. Let $e \in E(T(m))$ is not incident with a leaf. Such edge there exists because $\operatorname{diam} T(m) \geq 4$. Let $T(m)=T\left(m_{1}\right) \cup\{e\} \cup T\left(m_{2}\right)$, where $m=m_{1}+$ $m_{2}+1$. Then $\operatorname{diam} T\left(m_{1}\right) \geq 2$ or $\operatorname{diam} T\left(m_{2}\right) \geq 2$. Suppose without loss of generality that $\operatorname{diam} T\left(m_{2}\right) \geq 2$. Let us consider the following possibilities: 1. $c(e)=A$. Then

$$
\sigma_{A(e)}(T(m))=\sigma_{(A, 2 B)} T\left(m_{1}\right) \sigma_{(A, 2 B)} T\left(m_{2}\right)
$$

2. $c(e)=2 B$. Then

$$
\begin{aligned}
\sigma_{2 B(e)}(T(m))= & \sigma_{2 B(e)}\left(T\left(m_{1}\right) \cup\{e\}\right) \sigma_{(A, 2 B)}\left(T\left(m_{2}\right)\right) \\
& +\sigma_{(A, 2 B)}\left(T\left(m_{1}\right)\right) \sigma_{2 B(e)}\left(T\left(m_{2}\right) \cup\{e\}\right)
\end{aligned}
$$

Therefore $\sigma_{(A, 2 B)}(T(m))=\sigma_{A(e)}(T(m))+\sigma_{2 B(e)}(T(m))$. Hence

$$
\begin{aligned}
\sigma_{(A, 2 B)}(T(m))= & \sigma_{(A, 2 B)} T\left(m_{1}\right) \sigma_{(A, 2 B)} T\left(m_{2}\right) \\
& +\sigma_{(A, 2 B)}\left(T\left(m_{1}\right) \cup\{e\}\right) \sigma_{(A, 2 B)}\left(T\left(m_{2}\right)\right) \\
& +\sigma_{(A, 2 B)}\left(T\left(m_{1}\right)\right) \sigma_{(A, 2 B)}\left(T\left(m_{2}\right) \cup\{e\}\right)
\end{aligned}
$$

Since $\operatorname{diam} T\left(m_{2}\right) \geq 2$ then applying Lemma 1, we have

$$
\begin{aligned}
\sigma_{(A, 2 B)}(T(m)) \leq & \sigma_{(A, 2 B)}\left(P\left(m_{2}-1,1\right)\right) \sigma_{(A, 2 B)}\left(S\left(m_{1}\right)\right) \\
& +\sigma_{2 B(e)}\left(P\left(m_{2}-2,1\right)\right) \sigma_{(A, 2 B)}\left(S\left(m_{1}\right)\right) \\
& +\sigma_{(A, 2 B)}\left(P\left(m_{2}-1,1\right)\right) \sigma_{2 B(e)}\left(P\left(m_{2}-1,1\right)\right) \\
= & \sigma_{(A, 2 B)}\left(P\left(m_{2}-1\right) \cup S\left(m_{1}\right) \cup\{e\}\right) \\
= & \sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)
\end{aligned}
$$

which ends the proof.
Theorem 7. Let $m \geq 5$ be an integer. Then
$\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)=t\left(m_{1}+1\right) t\left(m-m_{1}-1\right)+t\left(m_{1}\right) t\left(m-m_{1}-2\right)$.
Proof. Let $e, e^{\prime} \in E\left(P\left(m_{1}, m-m_{1}-2\right)\right)$ be not incident with a leaf. If $c(e)=c\left(e^{\prime}\right)=2 B$ and a 2-path $e-e^{\prime}$ belongs to a partition of $2 B$ monochromatic subgraph into 2-paths, then we have $t\left(m_{1}\right) t\left(m-m_{1}-2\right)$ possibilities in this case. Otherwise the tree $P\left(m_{1}, m-m_{1}-2\right)$ can be considered as the union of two stars $S\left(m_{1}+1\right)$ and $S\left(m-m_{1}-1\right)$ and the result follows.

From the above theorems we have
Corollary 8. Let $m \geq 5, m_{1} \geq 2$ be integers, $T(m) \nsubseteq S(m)$ and $T(m) \nsubseteq$ $P\left(m_{1}, m-m_{1}-1\right)$. Then

$$
\sigma_{(A, 2 B)}(T(m)) \leq t\left(m_{1}+1\right) t\left(m-m_{1}-1\right)+t\left(m_{1}\right) t\left(m-m_{1}-2\right) .
$$

In the same way as for the palm $P\left(m_{1}, m-m_{1}-1\right)$, see [1], we can show the behavior of the parameter $\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)$ after moving an edge adjacent to a support vertex to another support vertex. So we omit the proof.
Lemma 2. Let $m \geq 6, m_{1} \geq 2$ be integers and $m_{1} \geq m-m_{1}-2$. Then

$$
\sigma_{(A, 2 B)}\left(P\left(m_{1}+1, m-m_{1}-3\right)\right)>\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right) .
$$

Theorem 9. Let $T(m)$ be a tree of size $m, m \geq 6, T(m) \nsubseteq S(m)$ and $T(m) \nexists P\left(m_{1}, m-m_{1}-1\right)$ for all $m_{1} \geq 2$. Then

$$
\sigma_{(A, 2 B)}(T(m)) \leq \sigma_{(A, 2 B)}(P(m-3,1))
$$

Proof. Let $T(m)$ be a tree of size $m, m \geq 6$ such that $T(m) \nexists S(m)$ and $T(m) \nexists P\left(m_{1}, m-m_{1}-1\right)$ for all $m_{1} \geq 2$. Then by Theorem 6 , $\sigma_{(A, 2 B)}(T(m)) \geq \sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)$ for all $m \geq 2$. If $m-m_{1}-2=1$, then $m_{1}=m-3$ and $P\left(m_{1}, m-m_{1}-2\right) \not \equiv P(m-3,1)$, so the result follows. Let $m-m_{1}-2 \geq 2$ and without loss of the generality, suppose that $m_{1} \geq m-m_{1}-2$. Applying Lemma 2, we obtain

$$
\sigma_{(A, 2 B)}\left(P\left(m_{1}, m-m_{1}-2\right)\right)<\sigma_{(A, 2 B)}\left(P\left(m_{1}+1, m-m_{1}-3\right)\right) .
$$

If $m-m_{1}-3 \geq 2$, then we apply Lemma 2 until we obtain the palm $P(m-3,1)$, which ends the proof.

Let $T_{i}^{*}(m)$ be the $i$ th maximum tree of size $m$ in the class of 2 -palms $P\left(m_{1}, m-m_{1}-2\right)$ for $m_{1} \geq 2$ with respect to the parameter $\sigma_{(A, 2 B)}(T(m))$. From the above considerations we have

Theorem 10. Let $m \geq 5$ be an integer. Then $T_{i}^{*}(m)=P(m-i-2, i)$ for $i=1,2, \ldots,\left\lceil\frac{m-2}{2}\right\rceil$.
